## COMS10017 Algorithms 2023/2024

### 1 Algorithm Design

Describe an  $O(n \log n)$  time algorithm that, given an array  $A$  of  $n$  integers and another integer  $x$ , determines whether or not there are two elements in  $A$  whose sum equals  $x$  (Hint: Sorting!).

### 2 O-Notation (Difficult)

Prove the following statement:

$$O(\log n) \subseteq O(2^{\sqrt{\log n}}) \subseteq O(n) .$$

To this end, identify a value  $n_0$  such that  $\log n \leq 2^{\sqrt{\log n}} \leq n$  holds, for every  $n \geq n_0$ . While the second of these two inequalities is easy to prove, the first requires an application of the racetrack principle.

**Remark:** The function  $2^{\sqrt{\log n}}$  grows faster than  $\log n$  (in fact, faster than any polylogarithm  $\log^c n$ , for any constant  $c$ ), but grows slower than  $n$  (in fact, slower than any polynomial  $n^\epsilon$ , for any constant  $\epsilon > 0$ ). The space between polylogarithms and polynomials is therefore non-trivial.

### 3 Mergesort

The Mergesort algorithm uses the MERGE operation, which assumes that the left and the right halves of an array  $A$  of length  $n$  are already sorted, and merges these two halves so that  $A$  is sorted afterwards. The runtime of this operation is  $O(n)$ .

Suppose that we replaced the MERGE operation in our Mergesort algorithm with a less efficient implementation that runs in time  $O(n^2)$  (instead of  $O(n)$ ). What is the runtime of our modified Mergesort algorithm?

### 4 Bubblesort

Bubblesort is a popular, but inefficient, sorting algorithm. It works by repeatedly swapping adjacent elements that are out of order:

1. What are the worst-case, best-case, and average-case runtimes of BUBBLESORT?
2. Consider the loop in lines 2 – 6. Prove that the following invariant holds at the beginning of the loop:

$$A[j] \leq A[k], \text{ for every } k \geq j .$$

Give a suitable termination property of the loop.

---

**Algorithm 1** BUBBLESORT

---

**Require:** Array  $A$  of  $n$  integers

```
1: for  $i = 0$  to  $n - 2$  do
2:   for  $j = n - 1$  downto  $i + 1$  do
3:     if  $A[j] < A[j - 1]$  then
4:       exchange  $A[j]$  with  $A[j - 1]$ 
5:     end if
6:   end for
7: end for
```

---

3. Consider now the loop in lines 1 – 7. Prove that the following invariant holds at the beginning of the loop:

The subarray  $A[0, i]$  is sorted and  $A[0, i - 1]$  consists of the  $i - 1$  smallest elements of  $A$ .

Give a suitable termination property that shows that  $A$  is sorted upon termination.

## 5 Optional and Difficult Questions

Exercises in this section are intentionally more difficult and are there to challenge yourself.

### 5.1 Closest Pair of Points (hard!)

The input consists of two arrays of  $n$  real numbers  $X, Y$  and represent  $n$  points with coordinates  $(X[0], Y[0]), (X[1], Y[1]), \dots, (X[n-1], Y[n-1])$ . Give a divide-and-conquer algorithm that finds the pair of points that are closest to each other, i.e., the output consists of a two indices  $i, j$  such that  $(X[i], Y[i])$  and  $(X[j], Y[j])$  are the two closest points.
